CS252 - Final Exam Study Guide

By: Zayd Hammoudeh

Lecture #01 – General Introduction

Reasons for Different Programming Languages

- 1. Different domains (e.g. web, security, bioinformatics)
- 2. Legacy code and libraries
- 3. Personal preference

Programming Language Design Choices

- 1. Flexibility
- 2. Type safety
- 3. Performance
- 4. Build Time
- 5. Concurrency

Features of Good Programming Languages

- 4. Safety (e.g. security and can errors be
 - caught at compile time)
 - 5. Machine independence
 - 6. Efficiency

Goals almost always conflict

Conflict: Type Systems

- Advantage: Prevents bad programs.
- Disadvantage: Reduces programmer flexibility.

Blub Paradox: Why do I need advanced programming language techniques (e.g. monads, closures, type inference, etc.)? My language does not have it, and it works just fine.

Current Programming Language Issues

1. Simplicity

2. Readability

3. Learnability

- Multi-core "explosion"
- Big Data
- Mobile Devices

Advantages of Web and Scripting Languages

- Examples: Perl, Python, Ruby, PHP, JavaScript
- · Highly flexible
- Dynamic typing
- · Easy to get started
- Minimal typing (i.e. type systems)

Major Programming Language Research Contributions

- Garbage collection
- · Sound type systems
- Concurrency tools
- Closures

Programs that Manipulate Other Programs

- Compilers & interpreters
- JavaScript rewriting
- Instrumentation
- Program Analyzers
- IDFs

Formal Semantics

- Used to share information unambiguously
- Can formally prove a language supports a given property
- Crisply define how a language works

Types of Formal Semantics

- Operational
 - Big Step "natural"
 - o Small Step "structural"
- Axiomatic
- Denotational

Haskell

- Purely functional Define "what stuff is"
- No side effects
- Referential transparency A function with the same input parameters will always have the same result.
 - o A function call can be replaced with its value and nothing will change.
- Supports type inference.

Duck Typing – Suitability of an object for some function is determined not by its type but by presence of certain methods and properties.

- o More flexible but less safe.
- Supported by Haskell
- o Common in scripting languages (e.g. Python, Ruby)

Side Effects in Haskell

- · Generally not supported.
- Example of Support Side Effects: File IO
- Functions that do have side effects must be separated from other functions.

Lazy Evaluation

- · Results are not calculated until they are needed
- Allows for the representation of infinite data structures

Lecture #02 - Introduction to Haskell

Key Traits of Haskell

- 1. Purely functional
- 2. Lazy evaluation
- 3. Statically typed
- 4. Type Inference
- 5. Fully curried functions

ghci - Interactive Haskell.

let - Keyword required in ghci to set a variable value. Example:

> let f x = x + 1 > f 3

4

Run Haskell from Command Line Use runhaskell keyword.

Lists

List Examples

> runhaskell <FileName>.hs

o last Last element in the list

the last one

Hello World in Haskell

main :: IO () main = do

> [1..4]

[1, 2, 3, 4]

putStrLn "Hello World"

Ranges • Can be infinite or bounded

• Use the "..." notation. Examples:

Primitive Classes in Haskell

- 1. Int Bounded Integers
- 2. Integer Unbounded
- 3.Float
- 6.Char
- 4.Double 5.Bool

- Base 0
- Comma separated in square brackets
- Operators
 - o: Prepend
 - ++ Concatenate
 - o!! Get element a specific index
 - o head First element in list
 - o tail All elements after head
- o take n Take first n elements from a

o init All elements in the list except

- o replicate 1 m Create a list of length 1 containing only m
- o repeat m Create an infinite list

> [1,2..6] [1, 2, 3, 4, 5, 6]

containing only m

> [1,3..10]

- [1, 3, 5, 7, 9]
- > [5, 4..1] [5, 4, 3, 2, 1]

Hello World in Haskell

putStrLn "Hello World"

main :: IO () main = do

- > putStrLn \$ "Hello " ++ "World" "Hello World"
- > let s = bra in s !! 2 : s ++ 'c' : last s : 'd' : s "abracadabra"

Infinite List Example

> let even = [2,4..]> take 5 even

[2, 4, 6, 8, 10]

1

```
List Comprehension
                                                                        A Simple Function
• Based off set notation.
                                                              > let inc x = x + 1
                                                              > inc 3
• Supports filtering as shown in second example
                                                                                                                  Pattern Matching
• If multiple variables (e.g. a, b, c) are specified, iterates through
                                                                                                    • Used to handle different input data
 them like nested for loops.
                                                              > inc 4.5
                                                                                                    • Guard uses the pipe ( ) operator
• Uses the pipe (|) operator. Examples:
                                                              5.5
                                                                                                    • Example:
> [ 2*x | x <- [1..5]]
                                                              > inc (-5) -- Negative
                                                                                                    inc :: Int -> Int
[2, 4, 6, 8, 10]
                                                                         Type Signature
                                                                                                      | x < 0 = error "invalid x"
> [(a, b, c) | a <- [1..10], b <-[1..10],
                                                              • Uses symbols ":: " and "->"
                                                                                                    inc x = x + 1
                  c \leftarrow [1..10], a^2 + b^2 = c^2]
                                                              • Example:
                                                              inc :: Int -> Int
 [(3, 4, 5), (4, 3, 5), (6, 8, 10), (8, 6, 10)]
                                                              inc x = x + 1
```

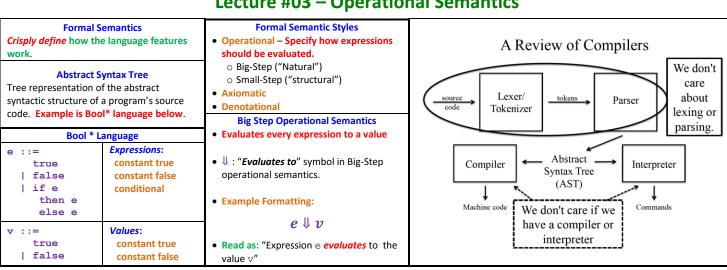

```
Recursion
• Base Case - Says when recursion should
                                                      Lab #01 – Max Number
                                                                                                       Reasons for a Large Number of
• Recursive Step - Calls the function with a
                                       > maxNum :: [Int] -> Int
                                                                                                          Programming Languages
 smaller version of the problem
                                       > maxNum [] = error "Invalid Input"

    Different domains

                                       > maxNum [x] = x
                                                                                                   • Different design choices
Example:
                                       > maxNum (x:xs) = if x > maxXs then x else maxXs
addNum :: [Int] -> Int
                                           where maxXs = maxNum xs
addNum [1] = 0
addNum (x:xs) = x + addNum xs
```

```
Recursion
                                                                  Haskell's Base Typeclasses
• :t or :type - Gets the type of a variable or function.
                                                          • Ord - Can be ordered
                                                          • Eq - Can perform equality check
Example:
                                                          • Show - Can convert to String
> :type 'A'
                                                          • Read - Can convert from String
'A' :: Char
                                                          • Enum - Sequentially Ordered
> :t "Hello"
                                                          • Bounded – Has upper and lower bound.
"Hello" :: [Char]
```

Lecture #03 – Operational Semantics

Small-Step Operational Semantics	Bool* Small-Step Operational Semantics Rules	
• Evaluate an expression until it is in <i>normal form</i>	E-IfTrue:	Example: Reduce the expression
		if (if true then false else true) then true else false
 Normal Form – Any form that cannot be 	if true then e_2 else $e_3 \rightarrow e_2$	
evaluated further.	E-IfFalse:	Step #1: Use rule "E-IfTrue" with "E-If"
 → : "Evaluates to" symbol in small step operational semantics. Example: 	if false then e_2 else $e_3 \rightarrow e_3$	if false then true else false
e ightharpoonup e' ightharpoonup e'	E-If:	Step #2: Use rule "E-IfFalse" (Now in normal form)
• $ ightharpoonup^*$: Many evaluation steps required. Example: $e ightharpoonup^* v$	$\frac{e_1 \to e_1'}{\text{if } e_1 \text{ then } e_2 \text{ else } e_3 \to \text{if } e_1' \text{ then } e_2 \text{ else } e_3}$	false

Bool* Extension: Numbers • 0 : The Number "0"

true false • succ 0: Represents "1" 0 • succ succ 0: Represents "2" | succ e pred e • pred n: Gets the predecessor v ::= true | false

Extended Bool * Language | if e then e else e | IntV IntV ::= 0 | succ IntV

Literate Haskell

• File Extension: ".lhs"

• Code lines begin with ">"

· All other lines are comments.

• "Essentially swaps code with comments."

Case Statement in Haskell

• Keywords: case, of, otherwise

Operator: ->

Example:

case x of val1 -> "Value 1" val2 -> "Value 2" otherwise -> "Everything else."

Lab #02 Review

```
Bool Expression Type
 data BoolExp = BTrue
        BFalse
>
        | Bif BoolExp BoolExp
        | B0
        | Bsucc BoolExp
>
        | Bpred BoolExp
    deriving Show
```

```
BoolVal Type
> data BoolVal = BVTrue
                | BVFalse
                | BVNum BVInt
    deriving Show
> data BVInt = BV0
               | BVSucc BVInt
>
    deriving Show
```

Type Constructors: BoolExp, BoolVal, BVInt

Non-nullary Value Constructors: Blf, Bsucc, Bpred, BVSucc, BVNum

Note: Even constants like BO, BTrue, BFalse, BVTrue, and BVFalse are nullary value constructors (since they take no arguments)

Lecture #04 – Higher Order Functions

Lambda

- Analogous to anonymous classes in Java.
- Based off Lambda calculus
- Example:

```
> (\x -> x + 1) 1
>(\x y -> x + y) 2 3
```

Function Composition

- Uses the period (.)
- f(g(x)) can be rewritten (f . g) x

Point-Free Style

- Pass no arguments to a function
- Example:

```
> let inc = (+1) - No args
> inc 3
```

Composition $> let f = (\x -> x - 5)$. $(\y -> y * 2)$ > f 7 9 > let f = ($x y \rightarrow x - y$) $(\z -> z * (-1))$

Example: Lambda with Function

Iterative vs. Recursive

- Iterative tends to be more efficient than recursive.
- Compiler can optimize tail recursive function.

Tail Recursive Function - The recursive call is the last step performed before returning a value.

Not Tail Recursive

```
public int factorial(int n) {
  if (n==1) return 1;
  else {
    return n * factorial(n-1);
```

Last step is the multiplication so not tail recursive.

Tail Recursive Factorial

```
public int factorialAcc(int n, int acc)
  if (n==1) return acc;
 else {
    return factorialAcc(n-1, n*acc);
}
```

Tail recursive code often uses the accumulator pattern like above.

Tail Recursion in Haskell fact' :: Int -> Int -> Int

fact' 0 acc = acc fact' n acc = fact' (n - 1) (n * acc)

Higher Order Functions

Functions in Functional Programming

- Functional languages treat programs as mathematical functions.
- Mathematical Definition of a Function: A function f is a rule that associates to each x from some set X of values a unique y from a set of Y values.

$(x \in X \land y \in Y) \rightarrow y = f(x)$

- f Name of the function
- X Independent variable
- y Dependent variable
- X Domain
- **Y** Range

Qualities of Functional Programming

- Functions clearly distinguish:
 - Incoming values (parameters)
 - Outgoing Values (results)
- No (re)assignment
- No loops
- · Return values depend only on input parameters
- Functions are first class values; this means they can:
 - Passed as arguments to a function
 - o Be returned from a function
 - o Construct new functions dynamically

Higher Order Function

Any function that takes a function as a parameter or returns a function as a result.

Function Currying

Transform a function with multiple arguments into multiple functions that each take exactly one argument.

Named after Haskell Brooks Curry.

Currying Example

addNums :: Num a => a -> a -> a

addNums is a function that takes in a number and returns a function that takes in another number.

map

- Built in Haskell higher order function
- Applies a function to all elements of a list.

filter

- Built in Haskell higher order function
- Removes all elements from a list that do not satisfy (i.e. make true) some predicate.

tolai

- Built in higher order function
- Does not support infinite lists.
- · Should only be used for special cases.

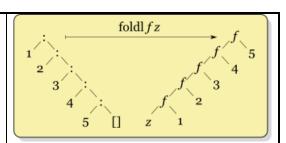

Example:

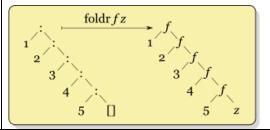

> foldl (
$$x y -> x - y$$
) 0 [1, 2, 3, 4] -10 -- (((0-1) - 2) - 3) - 4

foldr

- Built in higher order function
- Supports infinite lists.
- "Usually the right fold to use"

Example:

Thunk – A delayed computation

Due to lazy evaluation, foldl and foldr build thunks rather than calculate the results as they go.

foldl'

- Data.List.foldl' evaluates its results eagerly (i.e. does not use thunks)
- Good for large, but finite lists.

foldl in terms of foldr

myFoldl' f acc x = foldr (flip f) acc (reverse x)

Lecture #05 – Small-Step Operational Semantics

WHILE Language

 Unlike the Bool* language, WHILE supports mutable references.

e ::= a	Variable/addresses
l v	Values
a:=e	Assignment
e;e	Sequence
e op e	Binary Operations
if e then e	Conditional
else e	
while (e) e	While Loops
v ::= i	Integers
b	Boolean
op ::= + - *	/
>= > <=	I <

Small Step Semantics with State

 Since the WHILE language supports mutable references, the grammar must be updated to support it.

While Relation:

$$e, \sigma \rightarrow e', \sigma'$$

• σ – Store. Maps references to values.

Example Operations:

- $\sigma(a)$ Retrieves the value at address "a"
- σ[a := v] Identical to the original store
 with the exception that it now stores the
 value v at address "a"

Evaluation Order Rules

- Tend to be repetitive and clutter the semantics.
- Context based rules tend to represent the same information as evaluation order rules but more concisely.

Reduction Rule

Rewrites the expression. Example:

E-IfFalse:

if false then e2 else e3 \rightarrow e3

Context Rule

Specify the order for evaluating expressions. Example:

E-If:

 $\frac{e_1 \to e_1}{\text{if } e_1 \text{ then } e_2 \text{ else } e_3 \to \text{if } e'_1 \text{ then } e_2 \text{ else } e_3}$

Reducible Expression (Redex) – Any expression that can be transformed (reduced) in one step.

Example: Redex

if true then (if true then false else false) else true

This reduces to "if true then false else false"

Example: Not a Redex

if (if true then false else false) then true else true

Not a redex as expression "if true then false else false" must be evaluated first.

Evaluation Contexts

- Alternative to evaluation order rules.
- Marker (•) / hole indicate the next place for evaluation (i.e. where we will do the work).

Example:

C[r]

= if (if true then false else false) then true else true

r = **if** true **then** false **else** false

C = **if** • **then** true else true

C[**r**] is the original expression.

Rewriting Evaluation Order Rules Context based rules only apply to reducible

expressions (redexs). Example:

EC-IfFalse

 $C[if false then e_2 else e_3] \rightarrow C[e_3]$

Context Syntax

Data.Map

- Library: import Data.Map as Map
- Immutable
- Example Methods:
 - o Map. empty Creates and returns an empty map
 - Map.insert k v m-Inserts a value "v" at key "k" into map "m". Returns a new, updated map.
 - Map.lookup k m Returns the value at key "k" in map "m". Wrapped in a Maybe.
 - Map.member k m Returns true if k is in map "m" and false otherwise.

Precondition – Text above the line in a rule.

Context Rule for Binary Op:

$$\frac{v_3=v_1 \text{ op } v_2}{C[v_1 \text{ op } v_2] \rightarrow C[v_3]}$$

How to Read a Small Step Semantic Rule: "Given <*Precondition>*, then <*LeftSideArrow>* evaluates to <*RightSideArrow>*."

Lecture #06 – LaTeX

TeX

- Created by Donald Knuth
- Domain specific language for typesetting documents.
- Precisely controls the interface of content.
- Type of Literate
 Programming Logic is
 in natural language and
 code is interspersed.
 "Mark code instead of
- "Mark code instead of marking comments."

LaTeX

- Developed by Leslie Lamport. Derives from TeX.
- Type of Domain Specific Language (DSL) A computer language that is specialized for a particular application domain.
- Enforces separation of concerns Design principle for separating a computer program into different sections, such that each section addresses a separate concern
 - o Example: LaTeX separates formatting from content.
- Literate Programming

Specify Document Type \documentclass {article}

Specify Title Block Content
\title{Hello World!}

Start Document

begin {document}

Generate Title from Title Information \title{Hello World!}

Close the Document \end{document}

```
Cross-Reference
\ref{<referenceName>}
```

Reference a Bibliography Citation
\cite{<citationName>}

Create a Reference
\label{<referenceName>}

Create a Bibliography
\bibliography{<bibFileName>}

Create a List
\begin{itemize}
\item Text for #1
\item Text for #2
\end{itemize}

Create Section with Label
\section{Section #1}
\label{sec:one}

Create Subsection with Label
\subsection {<SubsectionName>}
\label{sec:<refName>}

Use of Tilde (~)

Creates an undividable space so the text "Section~\ref{sec:one}" will appear on one line

BibTeX

- References are tedious to reformat and renumber.
- Reference details shorted in a "*.bib" file.

Create a Bibliography
\bibliography{biblio}

BibTeX filename for the example would be "biblio.bib"

Define Bibliography Style \bibliographystyle {plainurl}

```
BibTeX Article Reference Example

@article{citationName,
   author = {Donald Knuth},
   title = {Literate Programming},
   journal = {},
   year = {1984},
   volume = {27},
```

Lecture #07 – Types and Typeclasses

Maybe Type

- Example of an algebraic data type
- Enables behavior similar to null in Java
- Can be used to provide context.
- Used when:
 - o A function may not return a value
 - o A caller may not pass an argument
- Definition:

data Maybe a = Nothing
| Just a

Algebraic Data Type

A composite data

type (i.e. a type

Created via the

made from other

Maybe "Divide" Example

```
divide :: Int -> Int -> Maybe Int
divide _ 0 = Nothing
divide x y = Just $ x `div` y

> divide 5 2
2
2 divide 4 0
Nothing
```

DO NOT FORGET THE Just IN CORRECT SOLUTION

Maybe Map Example

```
import Data.Map

m = Map.empty
m' = Map.insert "a" 42 m
case (Map.lookup "a") of
  Nothing -> error "Element not in map"
  Just x -> putStrLn $ show x
```

 $number = \{2\},$

 $pages = {97-111},$

Since element may not be in the map, you need to use a maybe

Example Algebraic Data Type

k – Type parameter. Specifies a type not a value.

Node: Value Constructor that creates values of type "Tree k"

• Tree and Tree Int have no types since they themselves form a concrete

• Node does have a type:

```
> :t Node
Node :: (Tree k) -> (Tree k) -> k -> (Tree k)
```

Explanation: To make a complete Node object, you pass it two objects of type "Tree k" and another object of type "k" and that returns a "Tree k" object.

Partially Applying a Value Constructor

- Value constructors can be partially applied similar to functions.
 Example:
- > let leaf = Node EmptyTree EmptyTree
- > Node (leaf 3) (leaf 7) 5

This creates a three node tree with value 5 at the root and values 3 and 7 at the leaves.

- Type of the "+" Operator
- > :t (+) (+) :: (Num a) => a -> a -> a

Explanation: The plus sign takes two numbers of type "a" and returns an object of type "a".

Explanation: Since "3" has no explicit type, it can for now be any type that satisfies the "Num" type class.

Keyword: data

types).

- Examples:Either
 - o Maybe
 - o Tree

```
Typeclasses
                            Kinds
                                                                                                            Example: Make Maybe an Instance of Eq

    Similar to interfaces in Java.

                                                                                                            instance (Eq a) => Eq (Maybe a) of

    Like a contract.

                                                                                                                   (==) Nothing Nothing = true
                                                                   o Implementation details can be included

                                                                                                            a class constraint.
                             > :k Map
                                                                   o Example: Do not have any data
                             Map :: * -> * -> *
                                                                     associated with them.
• Keyword :k, :kind
                                                                                                            Class Constraint
                                       Maybe Kind
• Example:

    Simplify polymorphism.

                                                                                                            Operator: =>
                             > :k Maybe
                                                                                                            • Ensures that a type parameter satisfies some
                             Map:: * -> *
> :k Tree
                                                                Example: Eq Typeclass
                                                                                                              typeclass requirement.
Tree :: * -> *
                                     Map String Kind
                                                                class Eq a where
                                                                                                                           Kind of Typeclasses
                             > :kind (Map String)
Explanation: A Tree requires
                                                                      (==) :: a -> a -> Bool
                             (Map String) :: * -> *
one type parameter (e.g.
                                                                      (/=) :: a -> a -> Bool
                                                                                                            > :k Eq
Int) to be made a concrete
                                                                     x == y = not (x /= y)
                                                                                                            Eq :: * -> Constraint
                             Explanation: Map String is has one
                                                                     x \neq y = not (x == y)
type.
                             of the two type parameters filled so
                                                                                                            > :k Num
                             it has one less asterisk.
                                                                The last two lines in the type class definition
                                                                                                            Num :: * -> Constraint
                                                                allow the developer to program either (==) or
                                                                (/=) but not necessarily both.
                                                                                                            Note: Typeclasses are a class constaint (not a type)
                                                                                                            so their kind is different.
```

Lecture #08 – Functors

```
Functor – Something that can be mapped over.
                                                                                          Examples: map and fmap on Lists
        Functor Type Class Definition
                                             • Handles things "inside a box"
                                                                                                                           Examples: fmap on Maybes
                                                                                          > map (+1) [1, 2, 3]
class Functor f where
                                              Example: List ([]) as an instance of Functor
                                                                                          [2, 3, 4]
  fmap :: (a \rightarrow b) \rightarrow f a \rightarrow f b
                                                                                                                           > fmap (+1) (Just 3)
                                                                                                                           Just 4
                                                                                          > fmap (+1) [1, 2, 3]
                                             instance Functor [] where
This is very similar to the definition of the
                                                                                          [2, 3, 4]
                                                fmap = map
                                                                                                                           > fmap (+1) Nothing
higher order function "map"
                                                                                                                           Nothing
                                                                                          > fmap (+1) []
                                             Explanation: map is a specialized version of
map :: (a -> b) -> [a] -> [b]
                                                                                          []
                                             fmap for lists.
```

```
Example: Either as an Instance of Functor
                                                     Either Algebraic Data Type
Example: Maybe as an Instance of Functor
                                                                                       instance Functor (Either a) where
                                           data Either a b = Left a
                                                                                          fmap = (Left x) = Left x

fmap f (Right y) = Right (f y)
                                                              | Right b
instance Functor Maybe where
                                                   deriving (Eq,Ord,Read,Show)
   fmap _ Nothing = Nothing
   fmap f (Just x) = Just (f x)
                                                                                       > fmap (+1) Leftt 20
                                           • Left - Error type that is not mappable.
                                                                                       20 -- No Change
DO NOT FORGET THE Just IN VALID SOLUTION
                                                                                       > fmap (+1) Right 20
                                           • Right - Expected type
                                                                                       21 -- Changed
```

IO in Haskell

Haskell avoids side effects but they are inevitable in real programs.	Type Signature of the main Function in Haskell main :: IO ()	• do – Allows for the chaining of multiple IO/Monad commands together. Syntactic sugar for bind ">>="	
 Monads Related to Functors Compartmentalize side effects. 	Hello World in Haskell main = putStrLn "Hello World"	• <- Extracts data out of an IO/Monad "Box"	
• () o Unit type in Haskell	Type Signature of getLine getLine :: IO String	• return – Places data into an IO/Monad "Box"	

```
return in Haskell

• Unrelated to "return" in other languages
```

```
• Better described as "wrap" or "box"
```

Summary:

```
return - Boxes an IO (since IO is a
monad)
```

<- Unboxes an IO

```
Type of the Unit Type ()

• Base type

> :t ()
() :: ()

Type of return

> :t (return ())
(return ()) :: Monad m => m ()
```

Using IO as a Functor

```
main = do
     line <- fmap (++"!!!") getLine
    putStrLn line</pre>
```

Explanation: This function takes a string input from standard in and appends "!!!" at which point it prints it to the console.

Definition of IO as a Functor

Explanation: The action object is taken out of the IO box, the function "f" applied to it, and then returned to the IO box.

id Function

• Takes one input parameter and returns that input parameter unmodified. Examples:

```
> id 3
```

Monad is a typeclass.

> id "Hello World"
"Hello World"

Functor Laws

Functor Law #1: If we map the id function over a Functor, the Functor that we get back should be the same as the original Functor.

```
Examples: > fmap id (Just 3)
```

Just 3
> fmap id Nothing
Nothing
> fmap id [1, 2, 3]
[1, 2, 3]

Functor Law #2: Composing two functions and then mapping the resulting (composed) function over a Functor should be the same as first mapping one function over the Functor and then mapping the other one.

```
Law #2 Written Formally fmap (f \cdot g) = fmap f \cdot fmap g
```

The Functor laws are NOT enforced. They are good practice that makes the code easier to reason about.

Lecture #09 – Applicative Functors

Functor – Something that can be mapped over. Allow you to map functions over different data types. Examples:

- Maybe
- Either
- 10
- Lists
- <*>

Functors return boxed up values.

Functor Example

```
> fmap (+1) [1, 2, 3]
[2, 3, 4]
> let x = fmap (+) [1, 2, 3]
```

Explanation: In this case \mathbf{x} is: [(1+), (2+), (3+)]

Applicative Functor

• Requires the importing of a special library as shown below:

import Control.Applicative

Functions in Applicative Typeclass:

- pure Wraps/boxes a value
- <*>- Infix version of fmap. Is itself a Functor.

```
Example Uses of pure
> pure 7
7
> pure 7 :: Maybe Int
Just 7
```

> pure 7 :: [Int] [7]

Type Class Definition of Applicative

```
class (Functor f) => Applicative f where
    pure :: a -> f a
     <*> :: f (a -> b) -> f a -> f b
```

Only difference between <*> and fmap is that the function in <*> is boxed while it is not in fmap (see the green f).

Make Maybe an Instance of Applicative

```
instance Applicative Maybe where
  pure = Just
  Nothing <*> _ = Nothing
  (Just f) <*> x = fmap f x
```

Explanation: pure simply wraps the value in Just. No need to explicitly check if "x" is maybe as fmap will do that for you.

Examples of Applicative Maybe

```
> Just (+3) <*> Just 4
Just 7
> pure (+3) <*> Just 4
Just 7
> pure (+) <*> Just 3 <*> Just 4
Just 7
> (+) <$> Just 3 <*> Just 4
Just 7
Explanation: x <$> is fmap as an infix operator. It is NOT necessarily the same as pure x <*>. It should be based off
```

Applicative Functor Law #1.

Making [] an Instance of Applicative

```
instance Applicative [] where
  pure x = [x]
  fs <*> xs = [f x | f <- fs, x <- xs]</pre>
```

Explanation: The function is actually a list of functions so list comprehension is needed.

```
Example Use of Applicative on Lists
> (*) <$> [1, 2, 3] <*> [1,0,0,1]
[1,0,0,1,2,0,0,2,3,0,0,3]
```

> pure 7 7 -- No change > pure 7 :: [Int] [7]

Definition of IO as an Instance of Applicative

```
instance Applicative IO where
  pure = return
  a <*> b = do
    f <- a
    x <- b
    return (f x)</pre>
```

Example of Applicative IO	11010
import Control.Applicative	A function that simplifies the application of a normal function to two Functors.
<pre>main = do a <- (++) <\$> getLine <*> getLine putStrLn a</pre>	<pre>liftA2 :: (Applicative f) => (a -> b -> c) -> f a -> f b -> fc liftA2 f x y = f <\$> a <*> b</pre>

Example of liftA2	Applicative Functor Definition
> (:) <\$> Just 3 <*> Just [4]	
Just [3, 4]	A functor you can apply to
> liftA2 (:) (Just 3) (Just [4])	7 - 1 - 1 - 1 - 1 - 1
Just [3, 4]	other Functors.

Applicative Functor Laws

<pre>Law 1: pure f <*> x = fmap f x</pre>	Law 2: pure id <*> v = v	Law 3: pure (.) <*> u <*> v <*> w = u <*> (v <*> w)
<pre>Law 4: pure f <*> pure x = pure (f x)</pre>	Law 5: u <*> pure y = pure (\$y) <*> u	Similar to Functor Laws, these are not strictly enforced but are good practice to make it easier to reason about the code.

Monoids

	d: An associative binary function and a value ts as an identity with respect to that function.	Definition of Monoid Typeclass	
	•	class Monoid m where	
• x * 1 • lst ++ • x + 0	,	<pre>mempty :: m mappend :: m -> m -> m mconcat :: [m] -> m mconcat = foldr mappend mempty</pre>	

Monoid Rules

Rule #1:	Rule #2:	Rule #3:
mempty `mappend` x = x	x `mappend` mempty = x	<pre>(x `mappend` y) `mappend` z = x `mappend` (y `mappend` z)</pre>

Lecture #10 - Monads

	Problem with Functors: Do not support chaining of	Applicative Functor: A Functor that can be applied to other
Functor – Something that can be mapped over.	multiple commands. Example:	Functors.
Definition:		
	> fmap (+) (Just 3) (Just 4)	<pre>class (Functor f) => Applicative f where</pre>
instance Functor f where		(<*>) :: f (a -> b) -> f a -> f b
fmap :: (a -> b) -> f a -> f b	Returns an error since it cannot resolve (Just 3+)	
	and (Just 4)	Requires library Control.Applicative

```
Even with Applicative Functors, it is not possible to chain together multiple commands. Example:

> Just (+3) <*> Just (+4) <*> Just (+5)
Returns error

| Monads: Can chain through a series of functions.

| Example #1: Using Just | > (Just 3) >>= (\x -> Just (x + 4)) >>= (\y -> Just (y+5)) | 12

| Example #2: Using return | > (return 3) >>= (\x -> return (x + 4)) >>= (\y -> return (y+5)) | 12
```

```
Comparing <*> and >>=
                                                                      Example of <$>, <*> and >>=
Functor:
                                                              > (\x -> x + 1) < > Just 3
                                                                                                          Example: Implement applyMaybe that applies a
(<*>) :: Applicative f => f (a -> b) -> f a -> f b
                                                              Just 4
                                                                                                          function to a Maybe
                                                              > Just (x -> x + 1) <*> Just(3)
(>>=) :: Monad m => m a -> (a -> m b) -> m b
                                                                                                          applyMaybe :: Maybe a -> (a -> b) -
                                                              Just 4
                                                                                                          > (Maybe b)
                                                                                                          applyMaybe Nothing _ = Nothing
applyMaybe (Just x) f = Just (f x)
Differences:
1. Order of the arguments changed.
                                                              > (Just 3) >>= (\x -> Just(x+1))
2. The function is boxed in Functor but not Monad
3. Monad function returns a boxed result.
                                                              Just 4
```

```
applyMaybe Nothing _ = Nothing
                                                        `applyMaybe` (\y -> Just (y-1))
applyMaybe (Just x) f = Just (f x)
                                            Nothing
          Monad Typeclass Definition
                                                                  Example a Robot Moving Towards a Goal (Not Failure)
                                                                              -- Define Operator and start location
                                                                              x -: f = f x
class Monad m where
                                            --Location
      return :: a -> m a
                                            type Robot = (Int, Int)
                                                                              start = (0, 0)
      (>>=) :: m a -> (a -> m b) -> m b
                                            -- Functions
                                                                              > start -: up -: right
      (>>) :: m a -> m b -> m b
                                            up (x,y) = (x, y+1)
                                                                              (1, 1)
      x \gg y = x \gg (\ -> y) --Lamda
                                            down (x,y) = (x, y-1)
                                            left (x,y) = (x-1, y)
                                                                              > start -: up -: left -: left -: right -: down
      fail :: String -> m a
                                            right (x,y) = (x+1, y)
      fail msg = error msg
```

Chaining applyMaybe

Additional Names for Monoids

• "Programmable Semicolons"

• "Applicative Functors you can chain."

> (Just 3) `applyMaybe` (_ -> Nothing)

Just 5

Example: Implement applyMaybe that applies a

applyMaybe :: Maybe a -> (a -> Maybe b)

-> (Maybe b)

function to a Maybe

```
Example a Robot Moving Towards a Goal (with Failure)
                                      -- Once the goal is reached,
                                      -- the robot stops
                                      goal := Map.empty
                                                                                 start = (0, 0)
                                              -: (Map.insert (0, 2) True)
Maybe as an Instance of the Monad Typeclass
                                              -: (Map.insert (-1, 3) True)
                                              -: (Map.insert (-3, -8) True)
                                                                                 > return start >>= up >>= left >>= left
instance Monad Maybe where
                                                                                                >>= right >>= down
                                     moveTo :: Pos -> Maybe Pos
                                                                                 Just (-1, 0)
     return = Just
                                     moveTo p = if Map.member p goal
                                                                                 > return start >>= left >>= left >>= up
                                                       then Nothing
     (>>=) Nothing
                      = Nothing
                                                                                                else Just p
     (>>=) (Just x) \overline{f} = f x
                                                                                                >>= right >>= right >>= down
                                                                                 Nothing
                                      -- Since these are in bind, no need
     fail _
                      = Nothing
                                      -- to handle Nothing. Bind handles it.
                                     up(x,y) = moveTo(x, y+1)
                                                                                 Explanation: Reached one of the goals (-1, 3) at the red up
                                      down (x,y) = moveTo (x, y-1)
                                      left (x,y) = moveTo (x-1, y)
                                      right(x,y) = moveTo(x+1, y)
```

Integer Division Using Monads

```
Integer Division with Bind with "do"
                                                                                                            Integer Division with Bind with "do" and return
       Integer Division with Bind and No "do"
                                                    mydiv :: Maybe Int -> Maybe Int -> Maybe Int
                                                                                                        mydiv :: Maybe Int -> Maybe Int -> Maybe Int
mydiv :: Maybe Int -> Maybe Int -> Maybe Int
                                                    mydiv x y = do
                                                                                                         mydiv x y = do
mydiv x y = x >>= (\numer ->
                                                                 numer <- x
                                                                                                                      numer <- x
             y >>= (\denom ->
                                                                 denom <- y
                                                                                                                      denom <- y
             if denom > 0
                                                                 if denom > 0
                                                                                                                      if denom > 0
                 then Just (div numer denom)
else fail "Div by zero"))
                                                                       then Just (div numer denom)
                                                                                                                         then return $ div numer denom
                                                                       else fail "Div by 0"
                                                                                                                         else fail "Div by 0"
```

List Monad

```
Making List an Instance of Monad
                                                                Example Use of List as a Monad
instance Monad [] where
                                                        listOfTuples :: [(Int, Char)]
        return x = [x]
                                                                                                                Combining a Maybe and a List Monad
                                                        listOfTuples = do
         (>>=) xs f = concat(map f xs)
                                                                        n <- [1, 2]
        fail _
                     = []
                                                                                                         > Just [2,3] >>= (\x -> Just(fmap (+1) x))
                                                                        ch <- ['a', 'b']
                                                                                                         [3, 4]
                                                                        return (n, ch)
Explnation: concat is needed here as f returns elements
                                                        > listOfTuples
already in a list. As such, concat merges the individual lists
                                                        [(1, 'a'), (1, 'b'), (2, 'a'), (2, 'b')]
(from each call to f) into a single list.
```

Lecture #11 – Parsing Combinators

Semantics: Enumerate what a program means. Defined by the interpreter or compiler.	Compilation Flow Step #1: Tokenizer/lexer generates a set of tokens.	Converts the characters of the program into words of the language.
Syntax: Enumerate how a program Is structured. Defined by the lexer and parser.	Step #2: Parser turns the tokens into an abstract syntax tree. Step #3: Compilers and interpreters convert the AST into machine code or commands respectively.	Examples: • Lex/Flex (C/C++) • ANTLR & JavaCC (Java) • Parsec (Haskell)

Lexer

Categories of Tokens

- Reserved Words/Keywords.
 - o Examples: while, if, then, else
- Literals/Constants.
- o Examples: 123, "Hello World!"
- · Special symbols.
 - o Examples: ";", "=>", "&&"
- Identifiers.
 - o Examples: "balance", "myFunction"

Parsing

- · Parser converts tokens to abstract syntax trees.
- Defined by context free grammars (CFG)
- Types of Parsers:
 - o Bottom-up/Shift-Reduce Parsers
 - o Top-down parsers

Context Free Grammars

- · Grammars specify the language.
- Specified in Backus-Naur form format. Example:

```
Expr -> Number
    Number + Expr
```

- Terminal Cannot be broken down further.
- Non-terminals Can be broken down further.

Example: "0", "1", "2", ..., "9" are terminals but digit, number, and expression are not.

Example Grammar

```
expr -> expr + expr
        expr - expr
        (expr)
        number
number -> number digit
        | digit
digit -> 0 | 1 | 2 | ... | 9
```

Bottom-Up / Shift-Reduce Parser

- Shift tokens onto a stack
- Reduce the stack to a non-terminal.
- LR Left to right, Rightmost derivation
- LALR Look-Ahead LR parsers are the most popular type of LR parsers.
 - o Examples: YACC/Bison
- · Fading from popularity

Top-Down Parser

- Non-terminals are expanded to match tokens.
- LL <u>Left</u> to right, <u>Leftmost derivation</u>
- LL(k) Parser Looks ahead up to k elements. **Examples:** Java CC, ANTLR
 - o The higher the k, the more difficult language is to parse. k can be arbitrary.
 - o LL(1) Easy to parse using either LL or recursive descent parsers. Many computer languages are designed to be LL(1).

Parser Combinator

Combine simpler parsers to make a more complex parser.

Example: Parsec

Useful Parsec Functions

- many Parses zero or more occurrences of the given parser.
- many1 Parses 1 or more occurrences of the given parser.
- noneOf Anything but the specified value
- spaces Whitespace characters
- char The specific specified character
- **string** The specific specified string.
- sepBy Separate tokens by some token.

```
Example Parsec Code
                                             import Text.ParserCombinators.Parsec
import Text.ParserCombinators.Parsec
                                             num :: GenParser st Integer
num :: GenParser st String
```

num = many1 digit

main = doprint \$ parse num "Hello" "42" str <- many1 digit return \$ read str

main = do

print \$ parse num "World" "42"

- st "State." Always required for our purposes.
- String/Integer Parser return type
- many1 Select one of more digits.
- digit 0, 1, 2, 3, ..., 9 (terminal)
- num Parser entry function
- "42" String to parse.

```
Example with try, <|>, and <?>
```

```
eol = try (string "\n")
   <|> string "\n\r"
   <?> "end of line"
```

- try If an incomplete match is found, rewind.
- <|> "Or" Operator for matching tokens.
- <?> Otherwise with an accompanying error message.

- "Hello"/"World" Debug string.

Practice Midterm and Review Notes

Question #1	Question #2	Question #3	Question #4	Question #5
a. True	a. True	a. False – Big step	a. False – Imperative	a. True

CSV Parser Example

```
Verbose Approach
import Text.ParserCombinator.Parsec
import System.Environment
csvFile :: GenParser st [[String]]
csvFile = do
          arr <- many line
          char eof
          return arr
line :: GenParser st [String]
line = do
       result <- many1 cell
       char '\n'
       return result
cells :: GenParser st [String]
cells = do
        firstCell <- cellContents
nextCells <- remainingCells</pre>
        return (firstCell:nextCells)
cellContent :: GenParser st String
cellContent = many $ noneOf ", \n" -- Two characters
remainingCells :: GenParser st [String]
remainingCells = do
                  (char "," >> cells)
                  <|> return []
main = do
       args <- getArgs
       p <- parseFromFile csvFile "example 1" (head args)
       case p of
           Left msg -> error msg
           Right csv -> print csv
```

Miscellaneous

Kind of Show and show > :k Show Show :: * -> Constraint Type and Kind of show > :k show Error (A function not a type) > :t show

```
Lambda and ADT Combined
> (\x -> Just (x+1)) 1
Just 2
        Creating Type Alias
```

```
type String = [Char]
```

Allows for more readable code as developer can use a type name that makes more sense for a given application. Example: applyMaybe that takes a (Maybe a) and applies to it a function that takes a normal a and returns a (Maybe b)

```
applyMaybe :: (Maybe a) -> (a -> Maybe b) -> (Maybe b)
applyMaybe Nothing _ = Nothing applyMaybe (Just x) f = f x
```

Explanation: Since the function "f" already returns a Maybe, you do not need to re-box it. However, since it does not take a Maybe, you need to unbox the first input parameter.

```
Applying return to Items
```

```
> return 7 :: Maybe Int
Just 7
> return 7 :: [Int]
[7] -- Need Int or get an error
```

show :: (Show a) => a -> String

List comprehension is syntactic sugar for using lists as monads.

Conclusion: Behavior for return is the same as pure. Both put the object in the minimum default context that still yields that value.

Monads and Lambda

When trying to chain multiple functions together in a Monad, remember the Monad must return a boxed value. Hence, Lambda often work well as they simplifying boxing.

Applicative Typeclass - Allows you to use normal functions on values that have a context (i.e. are inside a Functor).

Monad: Given a value of type, a, in a context, m, apply a function that takes a normal value of type a and returns a value in the context m.

```
(>>=) :: (Monad m) => m a -> (a -> m b) -> m b
```

Monads are just applicative functors that support bind (>>=).

Key Difference: Applicative functors support normal functions that take and return unboxed values while Monads return boxed values.

return - Monad equivalent of "pure" for Applicative Functors.

Cannot use fmap in the definition of a Monad since fmap returns a boxed value while the function of the Monad returns a boxed value. Hence, if you used fmap with a Monad, you would return a double boxed value.

Functor Definitions

```
TO
                                                          Maybe
                 Lists
                                                                                  instance Functor IO where
                                           instance Functor Maybe where
                                                                                    fmap f a = do
instance Functor [] where
                                                   Nothing = Nothing
                                             fmap
 fmap = map
                                                                                               x <- a
                                             fmap f (Just x) = Just (f x)
                                                                                               return (f x)
```

Applicative Functor Definitions

Lists			
<pre>instance Applicative [] where pure x = [x]</pre>			
(<*>) fs xs = [f x f <- fs, x <- xs]			

```
Maybe
instance Applicative Maybe where
  pure x = Just x
  (<*>) Nothing _ = Nothing
(<*>) (Just f) x = fmap f x
```

```
instance Applicative IO where
  a <*> b = do
            f <- a
            x <- b
            return (f x)
```

Monad Definitions

Lists	Maybe	10
<pre>instance Monad [] where return x = [x] (>>=) xs f = concat \$ map f x fail _ = []</pre>	<pre>instance Monad Maybe where return x = Just x (>>=) Nothing _ = Nothing (>>=) (Just x) f = f x fail _ = Nothing</pre>	<pre>instance Monad IO where (>>=) a f = do</pre>

Lecture #12 - Introduction to JavaScript

JavaScript

- Developed at Netscape by Brendan Eichs in 10 days
- · Originally named "Mocha"
- Syntax similar to Java

Multi-paradigm JavaScript Supported programming paradigms:

- Imperative
- Functional
- Object-Oriented (through prototypes)

Where JavaScript is Run

- Client Side Versions
- o Runs on user machine
- Server-side Versions o IVM: Rhino & Nashorn ○ Node is

```
Example: Imperative JavaScript
```

Example: Functional JavaScript

```
function addList(list) {
 if(list.length == 0) {
   return 0:
 return list[0]
         + addList(list.slice(1));
}
```

slice(begin[, end]) - Takes a subset of an array from the "begin" index to the "end" (exclusive). If no "end" is specified, it takes all elements to the end of the list.

Example: Object-Oriented JavaScript

```
function Adder (amount) {
  this.amount = amount;
Adder.prototype.add = function(x){
             return this.amount + x;
var myAdder = new Adder(1)
var y = myAdder.add(7)
```

Adder - Name of a new constructor. Convention is to start constructors with a capital letter.

this - Not optional in JavaScript.

```
function addList(list) {
 var = i, sum = 0;
  for( i = 0; i < list.length ; i++){</pre>
   sum += list[i];
 return sum;
```

Example: Quirks of JavaScript

var x = 42; // Create with var

y = 7; // No error without var

function noReturnAdd(a, b) {

var c = noReturnAdd(x, y)

//Lambda Function var myLambda = function(x) {return x * x;} Node.is

function add(a, b){

return a + b;

a + b;

• Based off Google's V8 engine.

run outside the browser.

• npm - Package manager to get new packages.

// c is "undefined" since no return

Callback Function

• Functions in JavaScript are first class objects of type "Object".

• JavaScript runtime environment and library designed to

• Not executed immediately.

JavaScript supports both "null" and "undefined"

Printing to the Console in JavaScript

• Standard Approach:

```
console.log("...")
```

- o Not supported by all implementations.
- JVM based JavaScript Approach: print
- Solution to Support a Single Interface: var print = console.log

• Functions whose inner variables refer to independent (free) variables.

Closure Example

```
function getNextInt(){
  var nextInt = 0;
  return function(){
             return nextInt++;
        }() // Double paren
             // run the function
console.log(getNextInt()); // print "0"
console.log(getNextInt()); // print "1"
console.log(getNextInt()); // print "2"
```

Reading from a File with Callbacks in Node.js

```
var fs = require('fs')
fs.readFile('myFile.txt',
    function(err, data) {
      if(err)
        throw err:
        console.log("" + data);
console.log("All done")
"All done" prints before the file contents due
to callbacks.
```

```
Synchronous File IO in Node
var fs = require('fs')
var data =
fs.readFileSync('myFile.txt');
console.log("All done")
```

To eliminate callbacks, most function names can be appended with "Sync"

Undeclared Object Fields

Any undeclared object fields or uninstantiated variables are undefined.

var y; // Uninstantiated // Both print 'undefined' console.log(y)

console.log(myDog.name)

```
Creating a JavaScript Object
```

```
var myDog = {age : 3,
               weight: 100}
Every object is a map.
```

Adding a Field to a JavaScript Object

```
myDog['height'] = 45 // Add a new height field
                     // Note the single quotes
```

Adding a Function to a JavaScript Object's Prototype

```
myDog.speak = function() { console.log("Grr"); }
```

Delete a Function from a JavaScript Object's Prototype

delete myDog.speak

Prototypes

Object Prototypes

require - Includes the JavaScript package "fs"

```
JavaScript prototypes are just like any other object.
```

```
var dogPrototype = {
    speak: function(){
      console.log("bark!");
```

Defining an Object's Prototype

```
var rex = { name: "Rex",
            proto : dogPrototype}
```

Prototypical Inheritance: If an object does not have a method of field, JavaScript looks to the object's __proto__ object.

```
Add a Special "speak" Method to Rex
                                                                                  Effect of the "new" Keyword
                                                          function Cat(name, breed) {
rex.speak = function() {
                                                            var this = {}; // Add when new is used
               console.log("Grr");
                                                            this.prototype = Cat.prototype; // Also comes from new
             };
rex.speak(); // Prints "Grr"
                                                            this.name = name;
                                                            this.breed = breed;
                                                            this.speak = function(){console.log("meow");};
delete rex.speak;
// Prints "Bark!" from __proto__
                                                            return this; // Also comes from new
rex.speak();
                                                                                  No "return" in a Function
delete rex.speak; // Does nothing
rex.speak(); // Prints "Bark!"
                                                          function noReturnAdd(x, y){
                                                            x + y; // without "return"
Unspecified Function Arguments: In JavaScript, any unspecified function
                                                          // c is "undefined" since no return
argument defaults to "undefined".
                                                          var c = noReturnAdd(x, y)
                                                          console.log(c); // Prints "undefined"
```

```
Top Prototypes
                                                                                 require
                                   Iterating Using "forEach"
                                                                                                              Running from the Command Line
                            var arr = [1, 2, 3];
                                                                    • Used to import an external module in
Object.prototype - Top
                                                                      Node.is
                             // Print each element in array
                                                                                                          • Use the keyword "node" for Node.js.
of all object prototypes
                            arr.forEach(function(val){
                                                                                                            Example:
                                            console.log(val);
                                                                     • Can be stored in a variable. Example:
Function.prototype -
                                                                                                                $ node my_program.js
                            }
Top of all function prototypes.
                                                                       var net = require('net');
```

```
Example: Currying in JavaScript
                                                     Function.prototype.curry = function(){
        Example: Create an Object with a Constructor
                                                       // Take slice from the Array class' prototype
                                                       var slice = Array.prototype.slice;
var Droid = {
                                                       // Convert arguments to an array
 speak: function() {
                                                       var args = slice.apply(arguments);
            console.log("I am "
                                                       var that = this;
                         + this.name);
                                                       return function(){
                                                         return that.apply(null,
 create: function(name) {
               var clone = Object.create(this);
clone.name = name;
                                                                             arg.concat(slice.apply(arguments));
                                                     };
               return clone;
                                                     function add(x, y){
        },
                                                       return x + y;
};
                                                     var addOne = add.curry(1);
                                                     console.log(addOne(3)); // Prints "4"
```

Lecture #13 – Lambda Calculus

Expressions

e ::= x (Variables, immutable)
| λ x.e (Lambda abstraction)

| e e (Function application)

Note: Lambda (λ) is simply a function.

 $\mathbf{v} ::= (\lambda \ \mathbf{x.e})$ (Lambda abstraction)

Function Application

Given a function where **E** is a **complex expression**:

 $\lambda(x.E)v$

Then:

 $\lambda(x.E)v \to E[x \vdash > v]$

Hence, "v" replaces "x" in "E".

Lambda Calculus is a simple, Turing complete language. Hence it is equal in power to a Turing Machine.

Lambda calculus stops evaluating when the result is in **normal form**.

Small-Step Evaluation Order Rules for Lambda Calculus

Rule: SS-E1 Rule: S

 $\frac{e_1 \rightarrow e_1'}{e_1 \ e_2 \rightarrow e_1' \ e_2}$

 $\frac{e_2 \rightarrow e_2'}{(\lambda x. e) \ e_2 \rightarrow (\lambda x. e) \ e_2'}$

Rule: SS-Lambda Context

 $(\lambda x. e) v \rightarrow e[x \vdash > v]$

Optional Rule: Lazy SS-Lambda Context

 $(\lambda x. e) e_2 \rightarrow e[x \vdash > e_2]$

Evaluation Strategies

Strict Evaluation Strategies		Lazy Evaluation Strategies	
Call by Value: Pass a copy of a parameter	Call by Reference: Implicit reference (e.g., pointer) to the parameter is	Call By Name: Re-evaluate the argument each time it is used.	Call by Need: Memoizes parameter value after first use.

Language Equivalents of $(\lambda x. e)$		True and False in Lambda Calculus		
		True in Lambda Calculus:	True in Lambda Calculus:	
JavaScript:	Haskell:	$getFirstParam = tru = (\lambda x. \lambda y. x)$	$getSecondParam = fls = (\lambda x. \lambda y. y)$	
<pre>function(x) {return e;} (\x -> e)</pre>		Note: This returns the <i>first</i> parameter in the pair of values.	Note: This returns the <i>second</i> parameter in the pair of values.	

Conditional in Lambda Calculus

$test = \lambda cond \cdot \lambda then \cdot \lambda els. (cond then els)$

Example #1:

test(tru tru fls)

 λ cond. λ then. λ els. (cond then els)(tru tru fls)

 λ then. λ els. (tru then els)(tru fls)

λels.(tru tru els)(fls)

(tru tru fls)

 $(\lambda x. \lambda y. x)(tru fls)$

 $(\lambda y. tru)(fls)$

tru

Example #2:

test(fls tru fls)

 λ cond. λ then. λ els. (cond then els)(fls tru fls)

 λ then . λ els. (fls then els)(tru fls)

 λ els. (fls tru els)(fls)

(fls tru fls)

 $\lambda x. \lambda y. y (tru fls)$

 $\lambda y. y (fls)$

fls

Boolean And

 $andd = \lambda b. \lambda c. (b c fls)$

Pair

 $pair = \lambda f. \lambda s. \lambda b. (b f s)$

Pair – A tuple-like data structure in Lambda Calculus.

Working with a Pair in Lambda Calculus

First Element in a Pair

Second Element in a Pair

 $first = \lambda p. (p tru)$

 $second = \lambda p. (p fls)$

Note #1: In the case of both first and second, the term p must be a pair.

Note #2: Both of these rely on the tru or fls being substituted for the "b" in the pair data structure in term selecting either the first or second element.

Church Encoding Numerals

 $zero = \lambda s. \lambda z. z$ $one = \lambda s. \lambda z. s z$ $two = \lambda s. \lambda z. s s z$ $three = \lambda s. \lambda z. s s s z$

Successor Function

 $scc = \lambda n. \lambda s. \lambda z. s(n z)$

Example:

$$one' = scc zero$$

 $two' = scc one' = scc(scc zero)$

Plus in Lambda Calculus

 $plus = \lambda m. \ \lambda n (\lambda s. \ \lambda z. \ m \ s (n \ s \ z))$

Example: Use church encoding numerals

plus three two $\rightarrow^* \lambda s$. λz . (three s (two s z))

Fix Combinator

Omega – Infinite Loop

$$Omega = (\lambda x . x x) (\lambda x . x x)$$

$$fix = \lambda f. (\lambda x. f(\lambda y. x x y)) (\lambda x. f(\lambda y. x x y))$$

Note: Can be used to do factorial operations.

Usage:

$$fix(g x) = g(fix g)x)$$

Lecture #14 – JavaScript Scoping

Example: First Class Function

```
function makeAdder(x) {
  return function(y) {
      return x + y;
      };
}
var addOne = makeAdder(1);
// Prints "11"
console.log(addOne(10));
```

Example: Function Application

```
function makeAdderList(arr) {
  var i;
  var output = [];
  for(i = 0; i < output.length; i++) {
     // Need to create a new scope
     function() {
          // Can add to arr without append
          output[i] = function(y) {
                return arr[i] + y;
                };
        }
    }
}</pre>
```

JavaScript lacks block scope for the closure to be right, must create the function inside another function.

Block Scope – The scope (i.e. visibility) of a variable is limited to a specific block (e.g., for loop, if statement, etc.).

- Unlike most languages, JavaScript does not have block scope.
- To create a new scope, use an anonymous function.

Variable Hoisting – All variable declarations (i.e., use of "var") are treated as if they are at the beginning of the function.

"this" in JavaScript

this – Refers to the scope where the function is called.

- In Normal Function Calls this refers to the global "this"
- Object Methods The object itself.
- Constructor (using "new") The newly created object.
- Exceptions: apply, call, and bind. Inline event handles on DOM elements

Any time a new function is created, the other "this" is no longer in scope

Execution Context

Consists of three part:

- A Variable Object Container for variables and functions.
- Scope Chain Variable object plus parent scopes
- Context Object this

Global Context

- Top Level Context
- Variable object is known as the "global object"
- this Refers to the global object.

Any variable declared without var is added to the global context.

Function Contexts

- Activation or Variable Objects which include:
 - o Arguments passed to the function
 - o A special arguments object
 - o Local variables

```
apply, bind, call Example
```

```
x = 3;
function foo(y) {
    console.log(this.x + y);
}
foo(100); // Prints "103"
// Array passed for args
foo.apply(null, [100]);
// Update the context
foo.apply({x:4}, [100]);
// No array needed
foo.call({x:4}, 100);
// Create a new function
var bf = foo.bind({x:5});
bf(100);
```

- apply Calls a function with the arguments passed as an array.
- call Calls a function with the arguments passed in comma separated.
- bind Used to create a new function with a custom context.

Lecture #14.5 - JSLint and TypeScript

Issues in JavaScript

- No block scope
- Forgetting var can lead to unexpected behavior since variables become global.
- Operator "==" is not transitive.
- Switch/case statements require "break"

```
JavaScript Automatically Inserts Semicolons
```

```
function makeObject() {
  return // Semicolon inserted here
    madeBy: 'Austin Tech. Sys.'
}
var o = makeObject();
console.log(o.madeBy); // error
```

```
Function "parseInt" can Yield Unexpected Results
// Drops the " tons"
console.log("what do you get? "
             + parseInt("16 tons"));
// Prints just "1" due to the "Oh"
parseInt("101");
```

Behavior of "typeOf" typeOf - Returns a string. May yield unexpected results. typeOf 5 // "number"

```
typeOf "hi" // "string"
typeOf NaN // "number"
typeOf null // "object"
```

Behavior of "typeOfChar"

```
typeChar - Returns a string.
Classifies letters as "digits".
typeOfChar "5" // "digit"
typeOfChar "q" // "digit"
```

// "Other character"

typeOfChar " "

• A tool to write cleaner and safer JavaScript.

• Requires that "use strict" (with quotes) be added at the beginning of all

ISI int

- · Performs static code analysis.
- Helps catch common programming errors by requiring:
 - o Variables declared before they are used.
 - o Semicolons are always used.
 - o Double equals never used.
- Inspired by the "lint" tool

Benefits of Type Systems

- Tips for compilers
- Hints for IDEs
- Enforced documentation
- Prevent code with errors from running.

TypeScript

- Developed by Microsoft
- · Static type checker for JavaScript. • A new "superset" language
- of JavaScript with: Type annotations
- o Classes

• Compiles to JavaScript

Function Type Annotations in TypeScript

```
function greet(person: string) {
  console.log("Hello " +
person);
var user : string = "Vlad";
// Prints "Hello Vlad"
greet (user);
```

Types in TypeScript

```
• number
           (var pi : number = 3.14)
          (var b : boolean = true)
• boolean
• string
           (var greet : string = "hi")
• array
           (var lst : number[] = [1, 2])
• enum
• any (var a : any = 3; var b : any = "hi")
```

```
TypeScript Class
```

```
class Employee{
 name : string;
 salary : number;
 constructor(name : string, salary : number) {
    this.name = name;
   this.salary = salary;
 display() { console.log(this.name); }
var emp = new Employee('Jon', 50000);
emp.display();
```

Lecture #15 – Event-Based Programming and Cryptocurrencies

JavaScript Embedded in HTML

Create a button on a website that prints

Improved JavaScript in HTML

Adding an Event Listener

• If clicking a button should perform multiple functions, then an event listener should be used.

Removing an Event Listener

Event listeners can be removed by function name.
 Example:

Events in JavaScript

• JavaScript is single threaded.

Types of Keys

• Private Key: Known

only by the owner

• Public Key: Known

by everyone

An event must be run to completion before the next event handler can run.

Event Emitter

• Import the "events" module using the syntax

```
var ee =
require('events').EventEmitter;
```

Used to create event via the keyword "on".
 Example:

```
ee.on('die', function() {
          console.log("Died");
     });
```

 Invoking (emitting) an event using the keyword "emit" Example:

Create a TCP Server in Node.js Using Event Listeners

```
var net = require('net');
var eol = require('os').EOL;
var srvr = net.createServer();

// Add an event listener
srvr.on('connection', function(client) {
    client.write('Hello there!' + eol);
    client.end();
});
srvr.listen(9000);
```

telnet – Used to connect to a TCP server on the command line

127.0.0.1 - IP address of localhost

Cryptocurrencies

Digital Signature

Non-Repudiation – Involves associating actions or changes to a unique individual.

- Solution in Cryptocurrency: Digital signature.
- Procedure:
 - Step #1: Owner encrypts the message with his private key
 - Step #2: Use the public key to decrypt the message.
- Analogy: Enclosed Bulletin Board

Private Key Encryption

Used to transmit sensitive data to a specific recipient.

- Procedure:
- Step #1: A user encrypts his data using the recipient's public key.
- Step #2: The intended recipient decrypts the data using his private key.
- Analogy: A public mailbox. Anyone can put letters in, but only the mailman has the key to open the box.
- update Used to update the signature with the specified message contents. Each signature object can only be updated once.
- hex Specifies that the output should be in hexadecimal format.
- Sync Ensures that the file read is done immediately without relying on a callback.
- SHA "Secure Hash Algorithm"
- RSA Signature algorithm

Example: JavaScript Signer Example

```
var crypto = require('crypto');
var fs = require('fs');

// Constructor for a "Signer" object
function Signer(privKeyFile) {
    this.privKey = fs.readFileSync(privKeyFile).toString('ascii');
}

// Add a "signMessage" function to the Signer prototype
Signer.prototype.signMessage = function(msgFileName) {
    var msg = fs.readFileSync(msgFileName).toString('ascii');
    var sign = crypto.createSign('RSA-SHA256');

    return sign.update(msg).sign(this.privKey, 'hex');
}
```

Double Spending – Spend the same funds in multiple places.

Solutions to Prevent Double Spending:

- Centralized Authority Disadvantages include that the central authority would charge a fee and not everyone trusts central authorities.
- Decentralized Authority Broadcast transactions to everyone.

Ledger – Used to keep a **history of all transactions** and the funds held by all users.

```
Example: JavaScript Verifier Example
var crypto = require('crypto');
var fs = require('fs');
// Constructor for a "Verifier" object
function Verifier(publicKeyFile) {
  this.publicKey = fs.readFileSync(privKeyFile).toString('ascii');
}
// Add a "verifySignature" function to the Verifier prototype
Verifier.prototype.verifySignature = function (msgFileName,
                                                signature) {
            var msg = fs.readFileSync(msgFileName).toString('ascii');
            // Create a verifier
            var ver = crypto.createVerifier('RSA-SHA256').update(msg);
           // Verify signature matches the hash
            var legit = ver.verify(this.publicKey, signature, 'hex');
            return legit;
```

Bitcoin Mining

- Block Chain Defines the transaction history.
 Used to prevent double spending.
- Proof of Work Verification of the block chain.
- Miners hash transaction details plus a "proof" (i.e. nonce)
 Reward: New bitcoins are mined for the first to find a proof.
- Cost to *Derive* a Proof: 2^N where N is the number of the initial bits that must be "0" for the proof to be valid.
- Cost to Verify a Proof: A single hash
- Bitcoin protocol is designed to make mining more profitable than cheating.

Attributes of a Good Hash Function

Role of a Hash Function: Compress arbitrary length inputs to small, fixed length outputs.	One Way: Given an output "y", it is infeasible to find an "x" such that: $h(x) = y$	Collision Resistant: It is infeasible to find any "x" and "y" such that: $h(x) == h(y)$	Compression	Efficient
---	---	---	-------------	-----------

Lecture #16 – Typed Arith

Benefits of Type Systems

- Tips for compilers to make code more efficient.
- Tips for IDEs and other tools to make writing code easier.
- Enforced documentation.
- Prevent code with errors from running.

Typing Rules

Format:

e : T

Meaning: Expression e falls into one of two categories:

- 1. e evaluates to a value of type T
- 2. Goes into an infinite loop.

The Typed Arith Language

iszero e

| pred e

| nv n ::= 0 | succ nv

T ::= Bool | Int

Good and Bad Typing Systems

- Good type systems prevent "bad" programs from running.
- Bad type systems prevent valid programs from running.
- Typchecking In an expression "typechecks", the expression is either:
- o A value
- An evaluation rule reduces the expression to a different expression.

Type Safety = Progress + Preservation

Progress

A well typed expression does not "get stuck"

Formal Definition: Given that **e**:**T**, then either:

- 1. e is a value
- 2. There exists an e' such that e -> e'

Preservation

A well-type expression will not change its type during evaluation.

Formal Definition: Given that e: T and

e -> e', then:

e':T

Lecture #17 - Macros and Sweet.js

Basic Compiler Structure with C-Style Macros Example: C Preprocessor Example Macros • Short for "macroinstruction" #define PT 3.14159 Source **Expanded Tokens** #define SWAP(a,b) {int tmp=a;a=b;b=tmp;} Code Code • Rule specifies how an input Processor Tokenize sequence maps to a int main(void){ replacement sequence. int x = 4, y=5, diam = 7; double circum = diam * PI; SWAP(x,y) Macros in C } • Performed by a preprocessor C Preprocessor Output Abstract Compiler Syntax Interpretter • Rely on text substitution. int main(void) { Tree int x = 4, y = 5, diam = 7;• Embedded languages like PHP. double circum = diam * 3.14159; Ruby, etc. use a similar approach. {int tmp=x;x=y;y=tmp;} Machine Code Interpretter Problem with C Macros (Input) **Macros** in JavaScript Hygienic Macro – Any macro whose expansion is guaranteed not • No standard macro system for JavaScript // Macro should be on one line to cause the accidental capture of identifiers. • Sweet.js has been gaining interest. #define SWAP(a,b) {int tmp=a; · Recently redesigned. a=b: b=tmp;} **Syntactic Macros** Sweet.is • Derive from Lisp since Lisp programs are essentially one big AST. Borrows concepts from Racket. int main(void){ Source-to-source compiler (i.e., transpiler) for int x = 4, tmp = 5; • Work at the level of abstract syntax trees. JavaScript. SWAP (x,tmp) } · Examples of other JavaScript transpilers: · Powerful by expensive. o TypeScript **Problem with C Macros (Output)** CoffeeScript • Hygiene easier to address at the AST level. o Dart (includes its own VM) int main(void){ int x = 4, tmp = 5; · Project backed by Mozilla • Essentially a source-to-source compiler. { int tmp = x;a = tmp;**Basic Compiler Structure with Syntactic Macros Invoking Sweet.js** tmp = tmp;• From command line: } \$ sjs myfile.js -d out/ } Abstract **Abstract** Macro Hence, a variable name collision between **Syntax Syntax** Expander • Compiled files run normally (as shown below for Node): the two variables named "tmp". This is Tree Tree \$ node out/myfile.js known as "inadvertent variable capture" Keywords in Sweet.js **Concatenating Multiple Result Strings** Writing a Swap Function in Sweet.js This function squares a set of input variables. • let - Create a Sweet.js syntax swap = function(ctx){ variable.

```
syntax square = function(){
  var innerCtx = ctx.next().value().inner();
  // Start with empty results
  result = #``;
  while(let stx of innerCtx){
    result =
      result.concat(#`${stx}=${stx}*${stx};`);
  // Eat comma
  // Ignored if no comma present
  innerCtx.next();
  }
}
square(a, b, c); // Invokes the macro
```

Note #1: Use ".concat" to concatenate multiple result strings.

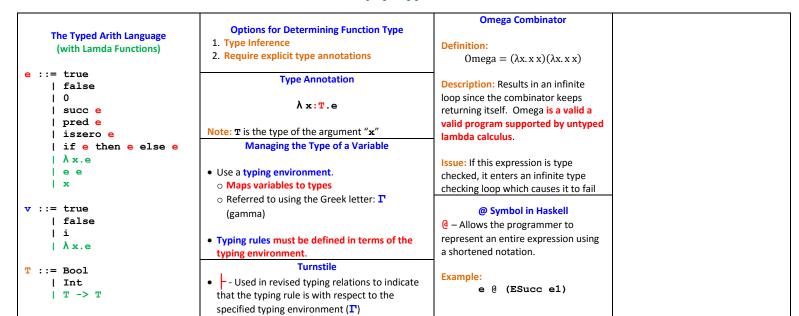

Note #1: If a token is not present, ".next()" does not cause an error.

- ctx.next().value() Get the next value from the context.
- #`...` Used to define a result string.
- concat Used to combine two result strings.
- let xxx of yyy Iterate over a list of tokens.
- isIndentifier Used to check if a Sweet.js variable matches some string.

A class in Sweet.js

```
syntax class = function(ctx){
 let className = ctx.next().value();
 let bodyCtx = ctx.next().value().inner();
  // By default assume empty constructor
 let construct = #`function() { }`;
let result = #``;
 while( let item of bodyCtx ){
    // Check if constructor
   if(item.isIndenifier('constructor')){
      // Get arguments then function code
      construct = #`function ${className}
                    ${bodyCtx.next().value()}
                    ${bodyCtx.next().value()}`;
   else {
     // Add the function to the class prototype
     result = result.concat(
         #`${className}.prototype.${item} =
             function ${bodyCtx.next.value()}
             ${bodyCtx.next.value()}`);
    // Return the constructor and methods
   return construct.concat(result);
```

Lecture #18 – Simply Typed Lambda Calculus

Arith Typing Rules Using a Typing Environment (Γ)				
[T-True]	Γ⊢ true: Bool	[T-If] $\Gamma \vdash e_1 : Bool, \ \Gamma \vdash e_2 : T, \ \Gamma \vdash e_3 : T$		
[T–False]	Γ⊢ false: Bool	$\frac{\Gamma \vdash if(e_1) \text{ then } (e_2) \text{ else } (e_3) : \Gamma}{\Gamma \vdash if(e_1) \text{ then } (e_2) \text{ else } (e_3) : \Gamma}$		
[T-succ]	$\frac{\Gamma \vdash e: Int}{\Gamma \vdash succ e: Int}$	[T-FunctionApplication] $\frac{\Gamma \vdash e_1 \colon T_1 \to T_2, \ \Gamma \vdash e_2 \colon T_1}{\Gamma \vdash e_1 \: e_2 \colon T_2}$ Note: e_1 is a function while e_2 is a parameter.		
[T–pred]	$\frac{\Gamma \vdash e: Int}{\Gamma \vdash pred e: Int}$	[T-LambdaVariable] $\frac{x \colon T \in \Gamma}{\Gamma \vdash x \colon T_2}$		
[T-iszero]	Γ⊢ e: Int Γ⊢ iszero e: Bool	$ \frac{ \Gamma \vdash x \colon T_1, \ \Gamma \vdash e \colon T_2 }{ \Gamma \vdash \lambda \ x. \ e \colon T_1 \to T_2 } $		

Lecture #19 – Metaprogramming and JS Proxies

Metaprogramming: Writing programs that manipulate other programs.

• Proposed in ECMAScript 6 for JavaScript.

Terminology in Reflection

- Introspection: Ability to examine (but not modify) the structure of a program.
- Self-modification: Ability to modify the structure of a program.

Introspection
Ability to examine (but not modify) the structure of a program.

JavaScript Examples Property Lookup

```
"x" in o; //o is an object

Iterate Over All Properties of an Object
for( prop in o ) {
    // Do something
```

```
Self-modification
```

Ability to modify the structure of a program.

JavaScript Examples

```
o["x"]; // Computed property
o.y = 42; // Add new property
delete o.y; // Delete property
// Reflected method call
O["m"].apply(null, [38]);
```

Proxies in JavaScript

- Metacircular Interpretation The language is able to understand its own language.
- Until recently, JavaScript did not support
- o Javascript proxies are intended to fix that.
- Node.js' implementation of proxies lags behind the standard.

intercession.

Proxies only exist for objects and functions.
 Proxies do not exist for primitives.

Proxies and Common Lisp

- Developed before object oriented languages were popular.
- Many libraries were create with non-standard OO systems.
- Common Lisp Object System (CLOS) – Standard object oriented system for Lisp.

Achieving Lisp Object Backwards Compatibility

Option #1: Rewrite all libraries using CLOS. Disadvantage

• Huge number of libraries.

}

• Not feasible to rewrite them all.

Option #2: Make a complex API

- API difficult to understand.
- Systems had conflicting features.

Option #3: Keep API simple and modify object behavior to fit different systems.

• This approach relies on **metaobject protocols**.

}

Proxies and Handlers

- The behavior of a proxy is determined by traps specified in its handler (i.e., the metaobject).
- Trap Methods that intercept an operation.
- Handler The metaobject that specifies the details of the trap. The handler itself is usually a normal object.
- Using proxies in node requires a special flag "--harmony-proxies". Example:
- \$ node --harmony-proxies prog.js

Kinds of JavaScript Proxies

• Object Proxies - Defined with:

Proxy.create(handler, proto)

• Functions (with extra traps) - Defined with:

• Proxies do not exist for primitives.

Read Only Handler

Information Control – Share a reference to an object, but do allow it to be modified.
 Example: Reference to the DOM.

```
function ReadOnlyHandler(obj){
  delete : function(name){
    return obj[name];
}

// rcvr can be ignored
  set : function(rcvr, name, val){
    return true;
}
```

```
A Noop Proxy – All Operations Passed through Unchanged
```

```
function handlerMaker(obj){
 // Delete a property from an object
 delete : function(name) { return obj[name]; },
 // Check if object has the specified property
 has : function(name) { return name in obj;},
 // Check if object (not prototype chain) has property
 hasOwn : function(name) {return Object.property
                                   .hasOwn(obj, name);},
 // Get a property value
 get : function(name) { return obj[name]; },
 // Set a property value
 set : function(rcvr, name, val) { obj[name] = val; },
 // Get all properties of an object
 enumerate : function(){
   var props = [];
   var prop:
   for(prop in obj) { props.push(prop); }
   return props;
 },
 // Get all of the keys of an object
 keys: function() { return Object.keys(obj); }
```

Aspect Oriented Programming

- Some code not well organized into objects. Example:
 - Cross-cutting concern where code is spread throughout a program.
- Canonical Example: Logging Statements
 - o Littered throughout the code
 - Swapping out a logger requires massive code changes.
- Solution: Use a proxy

Lecture #20 – Introduction to Ruby

Influences of Ruby

- SmallTalk
- o Everything is an object
- o Metaprogramming
- Perl
 - Regular Expressions
 - Function names

Ruby on Rails

- "Killer" app for Ruby o Lightweight web framework
 - o "Convention over configuration" - If use standard configuration, very little configuration required.
- Initial framework was PHP. but that was abandoned.

Basic Ruby Syntax

```
puts "Hello World"
a = [1, 2, 3]
m = { 'a' => "Apple",
      'b' => "Bear",
      'c' => "Cat" }
# Prints "1"
puts a[0]
```

Prints "Apple"

puts a['m']

Keywords

@ - Represents an object property

Returning From a Function

- Every function in Ruby returns a value, even if return is not used.
- If no return is specified, a function returns the last used

Basic Ruby Class

```
class Person
  # Constructor
 def initialize name # Parameter
    # Attribute
   @name = name
 end
 # Getter
 def name
   return @name
 end
  # Setter
 def name = newName
   @name = name
 end
 # Method
 def say_hi
   puts "Hi my name is #{@name}"
 end
end
```

```
Using Metaprogramming for Getters and Setters
class Person
  # Replaces getters and setters
  # Uses metaprogramming
  attr accessor :name
  # Constructor
  def initialize name
    # Attribute
    @name = name
  End
  # Method
  def say_hi
   puts "Hi my name is #{@name}"
  end
end
          Using a Class in Ruby
```

```
p = Person.new "Joe"
puts "Name is #{p.name}"
p.say_hi
#{...} - Embeds a variable in a Ruby String
```

Getters and Setters the Ruby Way

Relies on metaprogramming

- attr_reader Getter only
- attr writer-Setter only
- attr accessor Getter and setter

Reopening a Class in Ruby

- · Class definitions can be changed during runtime in Ruby.
- This is known as "reopening the class"

Parent Class

```
class Dog
  # Parentheses optional
  def initialize(name)
   @name = name
  end
  def speak
   puts "#{@name} says bark"
  end
end
```

Inheritance in Ruby

```
class GuardDog < Dog</pre>
  attr accessor :breed
  def initialize(name, breed)
    # Use parent constructor
   super(name)
   @breed = breed
  def attack
   puts "Grrr"
  end
end
```

Child Class

Note: Inheritance is doing using the less than (<) operator.

Mixin

- Add features to a class
- Similar to interfaces in Java with the exception that they can include functionality.
- module Keyword to define a Mixin.
- include Keyword to include a Mixin into a class.

Blocks in Ruby

Superficially similar to blocks in other languages.

- Create custom control structures.
- Can be represented with curly brackets ({...}) or do/end.

File IO without Blocks

```
file = File.open('test.txt','r')
file.each line do |line|
 puts line
end
file.close
```

Note #1: Similar "boilerplate" code of open and closing the file.

Note #2: It is possible one may forget to the close the file.

File IO without Blocks

```
File.open('test.txt','r') do |file|
 file.each line { |line|
   puts line
end
```

Note #1: Eliminates the "boilerplate" code.

Note #3: When using a block (both do/end, and curly brackets), surround the variable names in pipes (1).

Example: Mixin

```
# Define the mixin
module RevString
  def to rev s
    # Object is implicit
    to_s.reverse
 end
end
# Reopen the Person Class
class Person include RevSting
 def to s
    # Returns the value
    @name
 end
end
```

Dynamic Code Evaluation (eval)

- Executes source code dynamically
 - Code passed as either a string (or a block of code)
- Popular feature in JavaScript
 - Early usage was to convert JSON strings to variables since not supported by JavaScript.
- Source of security concerns.

Additional Ruby eval Methods

- instance_eval Evaluates code within an object's body.
 - o Access the internals of an object.
- class_eval Evaluates code within a class' body.
 - o Modifies the class' definition.
- Takes either a string or block of code. Block of code is more secure.

Example: Use instance_eval to Change an Object's Value

```
# Create with the name Bob
bob = Person.new "Bob"
```

- # Change his name
 bob.instance_eval do
 @name = "Steve"
- # Prints "Steve"
 puts bob.name

end

Regular Expressions in Ruby

- sub Replaces the first instance of a string match.
 - To perform the modification in place, must include an exclamation point (!) after sub.
- gsub Replaces all instance of a string match.
 To perform the modification in place, must include an exclamation point (!) after sub.

```
Example: class eval in Ruby
                                                                           Example: Using Regular Expressions in Ruby
# Applies to all classes
class Class
                                                         s = "Hi, I'm Larry; this is my" +
  # Simulate the "attr accessor" function
                                                              " brother Darryl, and this" +
  def my_attr_accessor(args)
                                                              " is my other brother Darryl."
    args.each do |prop|
                                                         s.sub(/Larry/,'Laurent')
      # Create getter
      self.class_eval("def #{prop};
                                                          # Prints s unchanged
                         return @#{prop};
                        end")
      # Create setter
                                                         # Changes first "Larry" to "Laurent"
      self.class eval("def #{prop} = v;
                          @\#\{prop\} = v;
                                                         s.sub! (/Larry/, 'Laurent')
                        end")
   end
                                                          # Prints first "brother" replaced with
  end
                                                          # "frere". s is unchanged, bt it did
end
                                                         # return the modified string.
# Use the new attribute
                                                         puts s.sub(/brother/, 'frère')
class Musician
 my attr accessor :name, :genre
                                                          # Same as previous except all where
                                                         # changed when printing.
end
                                                         puts s.gsub(/brother/, 'frère')
m = Musician.new
m.name = "Bob Marley"
puts m.name # Prints "Bob Marley"
```

Regular Expression Symbols in Ruby

	/\w/ - Any word character: [a-zA-Z0-9_]	/\d/ – Any digit character: [0–9]	/\w/ – Any whitespace character: [\t\r\n\f]
/./ - Any character except a newline	/\w/ – Any non-word character:	/\D/ – Any non-digit character:	/\W/− Any non-whitespace character:
	[^a-zA-Z0-9_]	[^0-9]	[^ \t\r\n\f]
⋆ – Zero or more times+ – One or more times		? – Zero or one times (optional)	

Important Syntax in Ruby

For Each Loop object.each do val end	Create a Mixin module Name end	Return from a Block def block_name yield x end	<pre>Single Line If Statement x = 5 # Does nothing x = 3 if (x > 10) puts x # Prints "5"</pre>	# Create array from 1 to 5 x = (15) Note: Uses parentheses.
irb – Command line for Ruby similar to GHCi.				

Lecture #21 – Blocks and Messages

Influence of Smalltalk on Ruby

Everything is an object

- Blocks
- Message passing

Benefits of Blocks in Ruby

- Create custom control structures
- Eliminate boilerplate code.
- Ruby blocks are closures, but they are different than JavaScript blocks.

Example: do noisy Block

```
def do_noisy
  puts "About to call block"
  yield # Calls block code
  puts "Just called block
end
```

Note: Called with a do/end or with curly brackets.

Example: Extend Array Class to Return Lowercase Version of Every Element

```
# Reopen the Array class
class Array
def each_downcase
    self.each do |val|
        yield val.downcase
    end
end
```

Example: Probabilistic Run Block

```
# Probabilistic Run Block
def with_prof(prob)
  yield if (Random.rand < prob)
end
with_prob 0.42 do
  puts "Prints 42% of time."</pre>
```

Example: Passing Code to a Block

```
def with_prob2(prob, &blk)
  blk.call if (Random.rand < prob)
end</pre>
```

blk – Block of code passed to the function.

Note #1: Argument name has an ampersand (&) before it.

Note #2: No ampersand is used when calling the block.

Example: Sharing Code Between Blocks

```
def half_the_time(prob, &blk)
  with_prob2(0.5, &blk)
end
```

Note: Need to pass argument to the function with the ampersand (&).

Example: with_prob in JavaScript

```
function with_prob(prob, f) {
  if(Math.random() < prob) {
    return f();
  }
}</pre>
```

Note: The JavaScript implementation relies on **callbacks**.

Example: Difference Between Ruby and JavaScript Blocks

```
Ruby

def coin_flip
  with_prob 0.5 do
    return "Heads"
  end
  return "Tails"
end
```

Note: This returns "Heads" half the time and "Tails" half the time.

 This is because a return in a Ruby block returns for the entire function.

JavaScript function coin_flip() { with_prob(0.5, function() { return "Heads";} return "Tails"; }

Note: This always returns "Tails"

• This is because even if "with_prob" runs, the return only occurs within the anonymous function.

Example: Probabilistic Run Block

```
# Probabilistic Run Block
def with_prof(prob)
   yield if (Random.rand < prob)
end
with_prob 0.42 do
   puts "Prints 42% of time."
end</pre>
```

Example: Passing Code to a Block

```
def with_prob2(prob, &blk)
  blk.call if (Random.rand < prob)
end</pre>
```

blk – Block of code passed to the function.

Note #1: Argument name has an ampersand (&) before it.

Note #2: No ampersand is used when calling the block

Example: Sharing Code Between Blocks

```
def half_the_time(prob, &blk)
  with_prob2(0.5, &blk)
```

Note: Need to pass argument to the function with the ampersand (&).

Singleton Classes

- In Ruby, every object has its own singleton class.
- This class holds methods and fields unique to that object.
- This is different from Singleton Objects in design patterns.

Example: Adding a Property to a Variable in JavaScript

```
function Employee(name, salary) {
   this.name = name;
   this.salary = salary;
}
var a = new Employee("Alice", 500);
var b = new Employee("Bob", 1000);

// Add a signing bonus to "Alice"
a.signingBonus = 2000;
```

Accessing Singleton Classes in Ruby

- To open an object's singleton class, use double less than symbols ("<<").
- Code only added to the specific object being reference.

Example: Adding a Property to an Object in Ruby

```
class Employee
  attr accessor :name,:salary
  def initialize(name, salary)
    @name = name
    @salary = salary
  end
  def to s
    @name # No return required
  end
end
# Create the Objects
a = Employee.new("Alice", 500)
b = Employee.new("Bob", 1000)
# Access the singleton class of "a"
class << a
  def signing bonus
   2000
  end
end
```

Example: Using a Singleton Class to Create Static Methods

```
# Add Static Methods to Employee Class
class Employee
  class << self
    def get_employee_by_name(name)
        @employee[name] # No return needed
    end
    # Called in constructor
    def add(emp)
        puts "Adding #{emp}"
        # Create map if not exist
        @employee = Hash.new unless @employee
        @employee[emp.name] = emp
    end
end</pre>
```

Message Passing

- Represents inter-object interaction.
- Sender Sends:
- Method name
- o Data: Method parameters (if any)
- Receiver:
 - o Processes the message
 - o (Optionally) returns data
- Receiver may not understand the message.

method missing

- Method that is part of every class. Can by overridden.
 - o Smalltalk Name: doesNotUnderstand
 - o Ruby Name: method_missing
- Invoked whenever an unknown method is called.

```
class Person
  attr_accessor :name
  def initialize(name)
    @name = name
  End
  # Called when method unknown
  def method_missing(m)
    puts "Didn't understand #{m}"
  end
end
```

Example: missing method in Ruby

Active Record and Message Passing

- Relational database tool in Ruby.
- Specify fields in the database to be extracted based off method names. Example:

Person.find_by_first_name "John"

Lecture #22 - Virtual Machines and Just-In Time Compilation

Virtual Machine Overview

- Code is compiled to bytecode o Byte code is low level o Platform independent
- The VM interprets the bytecode

Scheme

- Similar to an AST. Uses parentheses.
- Relies on a stack.

Supported VM Operations

- PUSH Adds an argument to the stack
- PRINT Pops an argument off the stack and prints it.
- ADD Pops two elements off the stack, adds them, and places result on the
- SUB Similar to add but for subtraction. If "A" is on the top of the stack and "B" is below it, the result is B - A
- MUL Similar to add but with multiplication.

Compilers vs. Interpreters vs. JIT

- Compiler
- o Efficient execution

Interpreter

- o Runtime flexibility
- o Efficient execution with runtime flexibility.

Just-In-Time Compliers

- Interpret code
- "Hot" (i.e., heavily-used) sections are compiled at runtime.

Advantages

- o Speed of compiled code
- o Flexibility of interpreter

Disadvantages

- o Overhead of compiler and interpreter
- o Complex implementation

Dynamic Recompilation

- JIT pursues aggressive optimizations o Makes assumptions about the code o Guard conditions verify assumptions
- Unexpected cases are interpreted (i.e., not compiled)
- Can in some corner cases outperform static compilation.

Types of JITs

- Method Based Compile Methods
- Trace Based Compile loops

How to Support JITs for a Language

- Option #1: Build your own JIT.
 - o Study the latest techniques
 - o Build large code bases to test.
 - o Profile the code execution
- Just-In-Time VM.

- Option #2: Use someone else's

Final Exam Review Notes

Parsec

- Parser combinator in Haskell.
- Example Question: Write a grammar a the level of the CSV parser.

JavaScript

- Prototype based language.
 - o Inherit from an object not from a class.
 - o Add properties and methods on the fly.
- Closure By wrapping an inner function with an outer function, the inner function can encapsulate variables.
 - o Have a scope chain.

Example: Write a Function that Toggles a Variable Each Time the Function is Called Example #2: Use a Closure

}();

Example #1: Use a Global

```
var b = true;
function flip(){
 if(b) b = false;
 else b = true;
 return b;
```

```
var flip = function(){
 var b = true;
 return function(){
   if(b) b = false;
   else b = true;
   return b:
```

// Needed to call out function

JavaScript - Multiparadigm Language

- Imperative
- Object Oriented
- Functional
 - o Supports higher order functions but not purely functional since not immutable.

JavaScript Scoping

- No block scope
- Variable declaration hoisting to the top of the function.

this in JavaScript

- In a method, this refers to the associated object.
- In a non-method, this refers to the global
- Constructor (with new) Refers to the object being created.
- DOM for Event Listeners Refers to the DOM
- apply, call, bind User can define what "this" refers to.

Scope Precedence in JavaScript

From highest to lowest precedence

- 1. Variable object (i.e., local variables)
- 2. Scope Chain
- 3. Global object (i.e., this)

Example: Scope Chain

```
function my_hello(){
 var x = 5;
  // Scope Chain
 function print hello(){
   console.log("Hello " + x);
 print_hello();
```

Quirks of JavaScript

- Semicolon insertion
- typeOf
 - o typeOf NaN Number
- o typeOf null Object
- == Not Transitive
 - \circ If a == b and b == c, it is not guaranteed that a == c

ISLint

- Designed to catch common JavaScript errors.
- Based off lint for the C language.
- Performs static code analysis

TypeScript

- Developed by Microsoft
- Source-to-source compiler (i.e., transpiler)
- Compiles to JavaScript
- Provides type annotation and classes.

Event Based Programming

• Relies on listeners

my_hello();

- Events are placed into an event queue.
- No concurrency.
- emit Invokes an event
- on Registers a listener
- Client-Based Programming Often used in GUIs.

Metaprogramming

- Reflection Two primary categories. Both occur at runtime. o Introspection – Examine program's execution at runtime.
- o Self-modification Modify a program execution at runtime.
- Intercession Trigger or control interaction at runtime.
- Reflection is more common, but intercession is more powerful.

Aspect-Oriented **Programming**

Designed to address crosscutting code (i.e., code that is interspersed everywhere in a program.

Metaobject Protocols

- Metaobject Any object that can reason about the behavior of other objects.
 - o Example: Proxies
- Handler
 - o Type of Meta Object.
 - o Defines traps.
- Trap Methods that intercept an operation.

Macros Sweet.js

- Source-to-source compiler (transpiler)
- Hygiene No inadvertent variable capture.
- Text Substitution Macro Works at the lexeme or text level.
- Syntactic Macro Works at the Abstract Syntax Tree (AST) level.

Lambda Calculus

- · Simple, Touring complete language.
- Based off anonymous functions (lambda)
- Expressions:

 $x \mid \lambda x . e \mid e e$

• Values:

 $\lambda x \cdot e$

Evaluation Strategies

- Strict Evaluation Strategies
 - o Call by Value Pass a copy of the parameter.
 - o Call by Reference Implicit reference (e.g., a pointer to the parameter is passed.
- Lazy Evaluation Strategies
- o Call by Name Re-evaluate the expression each time it is needed.
- Call by Need Evaluate when needed and memo-ize the result.

Advantages and Disadvantages of Type Systems

Renefits:

- Enforced documentation
- Tips for IDEs and Developers
- Prevent code with errors from running.

Disadvantage:

• May prevent valid code from running.

Simply-Type Lambda Calculus

- Relies on a typing environment (\(\Gamma \))
- Not Turing complete.

Type Safety – Two Components

- Progress Valid input continues to evaluation or reaches a value.
- Preservation Evaluation does not change the type of an object.

Influences of Ruby

- SmallTalk
 - o Everything is an object
- Blocks
- O Metaprogramming method missing and message passing.
- Perl
 - o Regular expressions
 - o Names of functions.

Goals of Ruby

- Object oriented scripting language.
- · Dynamically typed
- Interpreted.

Ruby Features

- eval Execute a string as code.
- Singleton Classes
 - No relation to singleton objects
 - o Class for a single object.
 - o Can be used to create static methods in a

Virtual Machine

- Source compiled to byte code.
- Byte code executed by an interpreter.

Interpreters vs. Compilers

- Interpreter Runtime flexibility
- Compiler Efficient code
- JIT Benefits *and* overhead of both an interpreter and compiler.

Just-In-Time Compiler

- Identify "hot" (i.e. frequently run) code.
- Optimize for most common cases and skip corner cases.
- o Guards protect for corner cases which are interpreted.
- May outperform statically compiled code.

```
var b = true;
function flip() {
    if(b) b = false;
    else b= true;
    return b;
}
var flip = function() {
    var b = true;
    return function() {
        if(b) b = false;
        else b = true;
        return b;
    };
```
